

# Inorganic Compounds Nomenclature (Year 8 & 9)

---

## 1. Formulation and nomenclature of inorganic compounds

(nomenclature is de systematic approach to naming chemical compounds)

There are two different ways to name inorganic compounds: systematic or stoichiometric, and common nomenclature.

- The systematic nomenclature indicates the number of atoms of each element in the formula by using Greek prefixes.(1-mono, 2-di, 3-tri, 4-tetra, 5-penta, 6-hexa, 7-hepta, 8-octa, 9-nona, 10-deca). The systematic nomenclature is often used to name binary compounds, but hardly used in any other cases.  
In some cases, the oxidation number of the cation can be indicated in roman between brackets when it has more than one oxidation number.
- The common nomenclature is only used for oxyacids and oxysalts. It uses accepted names. It is very simple and frequently used.

To work out the formula, simply identify the cation and anion and calculate the adequate sub index to get an overall zero charge for the compound.

### 1.1. Ions

Cations are named with the name of the element followed by the charge in parentheses:

$\text{Fe}^{2+}$ : iron (2+)

$\text{Na}^+$ : sodium (1+)

Anions are named with the -ide ending followed by the charge in parentheses, although this one can be omitted if there is no ambiguity:

$\text{Cl}^-$ : chloride

$\text{S}^{2-}$ : sulfide

### 1.2. Metallic hydrides

These are combinations of a metallic cation with the hydride anion ( $\text{H}^-$ ).

Two ways for the stoichiometric nomenclature:

- *metal name*(oxidation state in romans) hydride; if the metal has only one oxidation state, it is omitted.
- *metal name* prefix-hydride; if the metal has only one oxidation state prefixes can be avoided, and often mono- prefix too.

Examples:

$\text{LiH}$	lithium hydride	lithium hydride
$\text{PdH}_2$	palladium(II) hydride	palladium dihydride
$\text{FeH}_3$	iron(III) hydride	iron trihydride
$\text{AlH}_3$	aluminium hydride	aluminium trihydride

### 1.3. Non-metallic hydrides

These are combinations of non-metal simple anions with the  $\text{H}^+$  ion.

## Inorganic Compounds Nomenclature (Year 8 & 9)

---

There are two kind of non-metallic hydrides. The ones of the groups 13, 14, 15 and O have their own names that you have to know:

B <sub>2</sub> H <sub>6</sub>	borane
CH <sub>4</sub>	methane
NH <sub>3</sub>	ammonia

Hydrides of the other non-metals are gases that, when dissolved in water, have acid character and can be named with the prefix hydro- connected to the stem of the non-metal with an -ic suffix and ending with the word acid. When referring to the gases, then they are named with the word hydrogen followed by the name of the non-metal ended with the prefix -ide:

H <sub>2</sub> S	hydrosulfuric acid	hydrogen sulfide
H <sub>2</sub> Se	hydroselenic acid	hydrogen selenide
HF	hydrofluoric acid	hydrogen fluoride
HCl	hydrochloric acid	hydrogen chloride
HBr	hydrobromic acid	hydrogen bromide
HI	hydriodic acid	hydrogen iodide
	(note the -o- of prefix dropped)	

### 1.4. Metallic oxides

These are combinations of the oxide anion (O<sup>2-</sup>) with metallic cations. They have basic character, and, when reacted with water, produce hydroxides.

Their nomenclature is the same that for metallic hydrides, changing the word hydride for oxide:

FeO	iron(II) oxide	iron monoxide
Fe <sub>2</sub> O <sub>3</sub>	iron(III) oxide	diiron trioxide
Al <sub>2</sub> O <sub>3</sub>	aluminium oxide	aluminium oxide
Cu <sub>2</sub> O	copper(I) oxide	dicopper monoxide

### 1.5. Non-metallic oxides

These are combinations of the oxide anion (O<sup>2-</sup>) with non-metals, acting with some of their positive oxidation states. They have acid character, and, when reacted with water, produce oxyacids. They are formulated in the same way as the metallic oxides, and their nomenclature is also the same:

Cl <sub>2</sub> O	chlorine(I) oxide	dichlorine monoxide
Cl <sub>2</sub> O <sub>3</sub>	chlorine(III) oxide	dichlorine trioxide
Cl <sub>2</sub> O <sub>5</sub>	chlorine(V) oxide	dichlorine pentoxide
Cl <sub>2</sub> O <sub>7</sub>	chlorine(VII) oxide	dichlorine heptoxide
SO <sub>3</sub>	sulfur(VI) oxide	sulfur trioxide
SO <sub>2</sub>	sulfur(IV) oxide	sulfur dioxide

There are two metals that present a dual behavior, being able to act both as metals and non-metals; these are chromium and manganese. When chromium acts with the oxidations state +6 and manganese with +6 and +7, their oxides have acid character and produce oxyacids and anions like chromate or permanganate.

### 1.6. Binary salts

## Inorganic Compounds Nomenclature (Year 8 & 9)

---

Binary salts have a metallic cation and a simple non-metallic anion. They are named writing the name of the cation followed by the one of the anion.

NaCl	sodium chloride	sodium chloride
FeS	iron(II) sulfide	iron monosulfide
CoI <sub>3</sub>	cobalt(III) iodide	cobalt triiodide
NiN	nickel(III) nitride	nickel mononitride
Li <sub>2</sub> Se	lithium selenide	lithium selenide

### 1.7. Hydroxides

In the hydroxides, a metallic cation is combined with the hydroxide group, OH<sup>-</sup>, which formally acts on the whole with the oxidation state -1. They are named like the metallic oxides, changing oxide for hydroxide:

NaOH	sodium hydroxide	sodium hydroxide
Sn(OH) <sub>2</sub>	tin(II) hydroxide	tin dihydroxide
Mn(OH) <sub>3</sub>	manganese(III) hydroxide	manganese trihydroxide
Al(OH) <sub>3</sub>	aluminium hydroxide	aluminium trihydroxide

### 1.8. Oxyacids

Oxyacids are formed by the reaction of water with non-metallic oxides. They are formulated adding to the corresponding anion the ions H<sup>+</sup> needed to get a zero charge. **They are only named using a common nomenclature** by changing the anion endings -ite and -ate by -ous and -ic respectively and adding the word acid:

HClO	hypochlorous acid
HClO <sub>2</sub>	chlorous acid
HClO <sub>3</sub>	chloric acid
HClO <sub>4</sub>	perchloric acid
H <sub>2</sub> CO <sub>3</sub>	carbonic acid
H <sub>2</sub> SO <sub>3</sub>	sulfurous acid
H <sub>2</sub> SO <sub>4</sub>	sulfuric acid
HIO <sub>4</sub>	periodic acid
H <sub>3</sub> PO <sub>4</sub>	phosphoric acid
H <sub>2</sub> CrO <sub>4</sub>	chromic acid
H <sub>2</sub> Cr <sub>2</sub> O <sub>7</sub>	dichromic acid

### 1.9. Salts

Salts are formulated combining the ions that form them correctly. **They are only named using a common nomenclature:**

BrO <sub>3</sub> <sup>-</sup> + Au <sup>+</sup> = AuBrO <sub>3</sub>	gold(I) bromate
MnO <sub>4</sub> <sup>-</sup> + K <sup>+</sup> = KMnO <sub>4</sub>	potassium permanganate
CO <sub>3</sub> <sup>-</sup> + K <sup>+</sup> = K <sub>2</sub> CO <sub>3</sub>	potassium carbonate
ClO <sub>2</sub> <sup>-</sup> + Ca <sup>2+</sup> = Ca(ClO <sub>2</sub> ) <sub>2</sub>	calcium chlorite
CrO <sub>4</sub> <sup>2-</sup> + Cu <sup>2+</sup> = CuCrO <sub>4</sub>	copper(II) chromate
PO <sub>4</sub> <sup>3-</sup> + Al <sup>3+</sup> = AlPO <sub>4</sub>	aluminium phosphate
SO <sub>3</sub> <sup>2-</sup> + Fe <sup>2+</sup> = FeSO <sub>3</sub>	iron(II) sulphite
NO <sub>2</sub> <sup>-</sup> + Na <sup>+</sup> = NaNO <sub>2</sub>	sodium nitrite

### 2. Exercises

1.  $\text{ZnSO}_3$
2.  $\text{SrO}$
3.  $\text{Hg}_2\text{CO}_3$
4.  $\text{NO}_2$
5.  $\text{KBr}$
6.  $\text{CuOH}$
7.  $\text{PdH}_2$
8.  $\text{HIO}$
9.  $\text{K}_2\text{MnO}_4$
10.  $\text{Au}_2(\text{CrO}_4)_3$
11.  $\text{KIO}_4$
12.  $\text{HBrO}_3$
13.  $\text{Co}_2\text{O}_3$
14.  $\text{Ag}_2\text{O}$
15.  $\text{Pb}(\text{OH})_2$
16.  $\text{H}_2\text{Se}$
17.  $\text{H}_2\text{S}$
18.  $\text{Ni}(\text{OH})_2$
19.  $\text{BaSO}_3$
20. mercury(II) sulfide
21. zinc dichromate
22. ammonia
23. nitrous acid
24. phosphorus(III) iodide
25. copper(I) hydroxide
26. lead(II) iodate
27. iron(III) fluoride
28. gold(III) hydroxide
29. sodium hypochlorite
30. zinc chromate
31. nickel(II) nitrate
32. rubidium hydride
33. sulfurous acid
34. borane
35. methane
36. tin(II) chlorate
37. aluminium trichloride
38. nickel(III) iodide
39. nitrogen(III) oxide
40. cobalt(II) oxide
41. lead(IV) sulfide
42. sodium manganate

# Inorganic Compounds Nomenclature (Year 8 & 9)

## SYMBOL AND OXIDATION NUMBER OF THE MAIN CHEMICAL ELEMENTS

**Symbol:** how we represent the elements of the periodic table. Generally we represent the elements with one capital letter. If we use two letters, then the 2<sup>nd</sup> letter is always written in lower case. Ex: Hydrogen → H ; Nickel → Ni

**Valency (Oxidation number):** the number of electrons lost (positive on.), gained (negative on.), or shared (we assigned the negative on. to the most electronegative element), by an element when it combines with another.

Hydrogen H (on.=+/-1)

### Alkali metals (on.= +1)

Lithium Li  
Sodium Na  
Potassium K  
Rubidium Rb  
Caesium Cs  
Francium Fr

### Alkaline-earth metals (on.= +2)

Beryllium Be  
Magnesium Mg  
Calcium Ca  
Strontium Sr  
Barium Ba  
Radium Ra

### Earth metals (on.=+3)

Boron B  
Aluminium Al  
Gallium Ga  
Indium In  
Thallium Tl

### Group IV (on.=+2,+4)

Carbon C  
Silicon Si  
Germanium Ge  
Tin Sn  
Lead Pb

### Group V (on.=+/-3,+5)

Nitrogen N  
Phosphorus P  
Arsenic As  
Antimony Sb  
Bismuth Bi

### Group VI (on.=+/-2,+4,+6)

Oxygen O (on.= -2)  
Sulfur S  
Selenium Se  
Tellurium Te  
Polonium Po

### Halogens (on.=+/-1,+3,+5,+7)

Fluorine F (on.= -1)  
Chlorine Cl  
Bromine Br  
Iodine I  
Astatine At

### Noble Gases

Helium He  
Neon Ne  
Argon Ar  
Krypton Kr  
Xenon Xe  
Radon Rn

### Transition Metals

(on.=+1) Silver Ag

(on.=+2) Zinc Zn  
Cadmium Cd

(on.=+1,+2) Copper Cu  
Mercury Hg

(on.=+1,+3) Gold Au

(on.=+2,+3) Iron Fe  
Cobalt Co  
Nickel Ni

(on.=+2,+3,+6) Chromium Cr

(on.=+2,+3,+4,+6,+7) Manganese Mn

(on.=+2,+4) Palladium Pd  
Platinum Pt

Scandium Sc  
Titanium Ti  
Vanadium V
